Day 2

1 Call Expressions

In general a function is an operator that take in arguments and uses the arguments and returns or not return something.

Note. Arguemnts are evaluated left to right

```
[ ]: mul(add(2, mul(4, 6)), add(3, 5))
```

Figure 1: Check this later.  Got wrong in class. Note evaluated vs applied. Evalauated means lokoup where applied means given a value.

2 Names and Assignment Statments

We store values in a variable. The variable has a name and a value. Ceartin variable names are not allowed like unusal charchter  here what cant be included. You want names are that are descriptive but not too long.

Note. PYTHON is case senstive

Note. statments dont eval to values. Also recall namespace.

3 Converstion and Casting

Typecasting is turning one thing into a diffrent type using `int()` or `float()`. Any value can be turned into a string using `str()`

Using a print statment we can print things to the terminal, and in notebooks print statments allow us to print miltiple lines of things to the terminal. Print statments can take multiple arguments of diffrent types. Print means display statments give outputs.

Note. Multiple arguments vs string concatenation in print statments. String concatenation everything needs to be turned into a string and add the spaces for you while using multiple arguments will format for you.

NoneType, cells will not ouput the expressions that eval to None but it can be printed.

Note. CS61A If you seen an expression trying to print an print statments it will always eval to None.

We also had lab today.
