Day 6

1 Apply

Using the apply function we can reuse a function and apply it to all the columns: See example documentation. Does not change values of the table. ex: **weather.apply(celsius, 'High')**. Returns an array can simply pass the function too. Order of params matters too.

Note. To make change use with_column and pass the name and table.apply func.

*Note. What we could see in exam: **sat.with_column('Avg. Score', sat.apply(avg_score, 'Critical Reading', 'Math', 'Writing'))***

2 Scope

Definition 2.1. Scope is essentially the area in a program where a name can be accessed.

Recall global scope vs function/local scope. Always check this on mcq. Inside a local scope python always looks at local scope then global scope.
